Lambda Calculus Review

① λ calculus is a smallest, Universal Programming Language

②

name x
function $\lambda x. x$
function application $e_0 e_1$

grammar, define

the lambda calc calc

③ β -reduction : 3 steps

Identify

① Syntactic structure : formal parameters

actual parameters

function body

② Identify the occurrence of formal ~~one~~ parameter in the function body

③ replace (remove the λx + parenthesis)

Results?

(α -renaming)

$$\begin{array}{c} ((\lambda x. x) x) \rightarrow x \\ ((\lambda y. y) x) \rightarrow x \end{array}$$

Lambda Calculus Review

④ λ encoding

\Rightarrow^+ three

RefLang

Side Effect

- ▶ Pure functional programs can be understood in terms of their input and output. Given **the same input** a functional program would produce **the same output**.
- ▶ Change the state of the program besides its output
- ▶ Examples:
 - ▶ Reading or writing memory locations
 - ▶ Printing on console, reading user input,
 - ▶ File read and file write,
 - ▶ Throwing exceptions,
 - ▶ Sending packets on network,
 - ▶ Acquiring mutual exclusion locks, etc...

Two Concepts

- ▶ **Heap:** an abstraction representing area in the memory reserved for dynamic memory allocation
- ▶ **References:** locations in the heap

Design Decisions – Heap

Heap size is finite, programming languages adopt strategies to remove unused portions of memory so that new memory can be allocated.

- ▶ manual memory management: the language provides a feature (e.g. free in C/C++) to deallocate memory and the programmer is responsible for inserting memory deallocation at appropriate locations in their programs.
- ▶ automatic memory management: the language does not provide explicit feature for deallocation. Rather, the language implementation is responsible for reclaiming unused memory (Java, C#).

How individual memory locations in the heap are treated:

- ▶ untyped heap: the type of value stored at a memory location is not fixed, can be changed during program execution
- ▶ typed heap: each memory location has an associated type and it can only contain values of that type, the type of value stored at a memory location doesn't change during the program's execution

Design Decisions – Reference (pointers)

1. Explicit references: references are program objects available to the programmer
2. Implicit references: references only available to implementation of the language
3. Reference arithmetic: references are integers and thus we can apply arithmetic operations
4. Deref and assignment only: get the value stored at that location in the heap, assignment can change the value stored at that location in the heap

Examples:

- ▶ C Programming language: manual memory management, explicit reference, untyped heap, reference arithmetic
- ▶ Java: automatic memory management, deref and assignment only, untyped heap, implicit reference
- ▶ Reflang: manual memory management, deref and assignment, untyped heap, explicit references

$$\text{int } a = 2 \quad *(\text{P} + 20) = 100$$

malloc

free

$$*P = 2i$$

$$P = P + Q$$

$$\underline{*P} = z$$

$$i = \underline{*P}$$

↓ access object feature through a reference

Deref S.i

$$S.\underline{\text{toString}}() = S.i$$

S = New object()

Assignment

$$\underline{S.i} = 2$$

RefLang

- ▶ Expressions for allocating a memory location, dereferences a location reference, assign a new value to an existing memory location, free previously allocated memory location

- ▶ Examples:

$\$(\text{ref } 1)$

loc: 0

(ref ①)

- ▶ Value: the location at which memory was allocated (next available memory location)
- ▶ Side effect: assign value 1 to the allocated memory location
- ▶ Value and type are known from the expression

Reflang Expressions

ref: This expression evaluates its subexpression to a value, allocates a new memory location to hold this value, and returns a reference value that encapsulates information about the newly allocated memory location.

```
$ (define loc1 (ref 12))
```

// stores value 12 at some location in memory, creates a reference value to encapsulate (and remember) that location, and stores that reference value in variable loc1

```
$ (define loc2 (ref 45))
```

```
$ loc1 // check the reference value stored in variable loc1  
loc:0
```

```
$ loc2  
loc:1
```

Ref ~~Exp~~
~~Value~~

Set! loc1 loc2

\$ ~~loc~~ loc1

Reflang Expressions

loc:

deref: This expression evaluates its subexpression to a value. If that evaluation evaluates to a reference value, and that reference value encapsulates a location I, then it retrieves the value stored in Heap at location I.

94: |

loc 10

\$ (deref loc1) // gives the value stored at loc1
12

\$ (deref loc2) // gives the value stored at loc2
45

\$ (+ (deref loc1) (deref loc2)) //access both values and adds them
57

Reflang Expressions

assign: This expression is used to change the value stored on some location in Heap.

\$ (set! loc1 23) // previous value 12 is overwritten by 23
23

\$ (set! loc2 24) // previous value 45 is overwritten by 24
24

→ \$ loc1 // loc1 still has address 0 but value has changed now
loc:0

→ \$ loc2 // loc2 still has address 0 but value has changed now
loc:1

\$ (+ (deref loc1) (deref loc2)) // different value different summation
value

47

Reflang Expressions

free: This expression is used to deallocate the reference stored in Heap.

`$ (free loc1) // deallocates the memory address 0`

`$ loc1 // variable loc1 still points to same location loc:0`

`$ (deref loc1) // dereference loc1`

`Error:null // invalid because memory location has been freed`

`$ (free loc2) // deallocates the memory address stored in loc2`

`$ (deref loc2) // dereference loc2`

`Error:null // invalid because memory location has been freed`

RefLang: More Examples

```
$ (free (ref 1)) // delocate the memory location where 1 is stored  
$ (deref (ref 1)) // deref a memory location defined by ref 1  
$ (let ((loc (ref 1))) (deref loc))  
$ (let ((loc (ref 1))) (set! loc 2))
```

- ▶ ref, free, deref, set!

RefLang: More Examples

Pointer Value
loc q: !

(loc2) 14 2

set! loc loc2

q: [Pointer 14]

(cleref (defref loc)).

A reference expression is like the `malloc` statement in C, C++. It will result in a memory cell being allocated at the next available memory location. That location will contain value 1. The value of the reference expression is the location at which memory was allocated, here `loc:0`.

The reference expression is also different from `malloc` statement in C and C++. Unlike `malloc` that accepts the size of the memory that is to be allocated, the argument of the reference expression is a value that is to be stored at the newly allocated location. From this concrete value, both the type of the value and the size required to store it can be derived.

In Reflang language we can explicitly free a previously allocated memory location using the *free expression* as follows.

```
$ (free (ref 1))
```

A free expression is like its namesake in languages like C, C++. It will result in a memory at the location that is the value of the expression (`ref 1`) to be deallocated.

We can also dereference a previously allocated memory location using the dereference expression

```
$ (deref (ref 1))
```

```
1
```

```
$ (let ((loc (ref 1))) (deref loc))
```

```
1
```

Dereferencing a memory location is a way to find out what is stored at that location. So a dereference expression takes a single expression, expression that evaluates to a memory location, and the value of the dereference expression is the value stored at the memory location.

We can also mutate the value stored at a memory location using the assignment expression

```
$ (let ((loc (ref 1))) (set! loc 2))
```

```
2
```

```
$ (let ((loc (ref 3))) (set! loc (deref loc)))
```

```
3
```

```
$
```

An assignment expression `set!` has two subexpressions, left hand side (LHS) expression that evaluates to a memory location, and right hand side (RHS) expression that evaluates to a value, and the value of RHS expres-

Reflang: Grammar

Reflang: Extending Values

- ▶ **RefVal \neq NumVal**
 - ▶ prevent from accessing arbitrary memory location
 - ▶ no arithmetics
 - ▶ extra meta data

RefLang: Heap abstraction

"Map"

Heap : RefVal → Value

```
1 public interface Heap {  
2     Value ref (Value value) ;  
3     Value deref (RefVal loc) ;  
4     Value setref (RefVal loc, Value value) ;  
5     Value free (RefVal value) ;  
6 }
```

Reflang Expression Semantics

stack

- ▶ Expression do not affect heap directly or indirectly:
- ① Constant expression: value e env h = (NumVal n) h
n is a Number, env is an environment, h is a heap
- ② Variable expression – look up names for values: value (VarExp var)
env h = get(env, var) h
- ▶ Indirectly affect heap through their subexpressions
- ▶ Directly affect heap

revisit all the expressions

Reflang Expression Semantics: Indirectly affect heap

- ▶ the order in which side effects from one subexpression are visible to the next subexpression has significant implications on the semantics of the defined programming language.

- ▶ Add expression: / Sub / Multiplication

value (AddExp $e_0 \dots e_n$) env $h = v_0 + \dots + v_n, h_n$

if value e_0 env $h = v_0 h_0, \dots$, value e_n env $h_{n-1} = v_n h_n$

where $e_0, \dots, e_n \in \text{Exp}$, $\text{env} \in \text{Env}$, $h, h_0, \dots, h_n \in \text{Heap}$

a left-to-right order is used in the relation above for side-effect visibility

* An example of side effect in RefLang

inclass exercise

Reflang Expression Semantics: Directly affect heap

- ▶ ref, set!, free
- ▶ deref: read from memory only

Reflang: RefExp

value (RefExp e) env h = l, h_2
