## **Stochastic Process**

---

## Stochastic Processes

### Definitions

A *stochastic process* is a random variable that also depends on time. It is written as

$$X_t(\omega) = X(t, \omega) \text{ for } t \in \mathcal{T}, \omega \in \Omega$$

where  $\mathcal{T}$  is a set of possible times. e.g.  $[0, \infty)$ ,  $\{0, 1, 2, \dots\}$  and  $\Omega$  is the whole sample space.

- $X_t = X_t(\omega)$  is the random variable
- $t$  is time
- $\omega$  is the "state"
- The *state space* is the collection of values the R.V  $X_t$  can take on:  $\cup_{t \in \mathcal{T}} \text{Im}(X_t)$

2 / 16

## Types of Stochastic Processes

Types of Stochastic Processes:  $X_t(\omega)$  can be

- Continuous-time ( $t$ ) continuous-state ( $\omega$ )
- Discrete-time ( $t$ ) continuous-state ( $\omega$ )
- Continuous-time ( $t$ ), discrete-state ( $\omega$ )
- Discrete-time ( $t$ ), discrete-state ( $\omega$ )

We will only look at these two types

3 / 16

## Types of Stochastic Processes

### Examples:

1. Let  $X_t$  be the result of tossing a fair coin ( $0 = \text{tails}$ ,  $1 = \text{heads}$ ) in the  $t^{\text{th}}$  trial.

at each trial ( $t$ )  
 $X_t$  can take  
on values  
0 or 1

- The time (trial)  $t \in \mathcal{T}$  where  $\mathcal{T} = \{1, 2, 3, \dots\}$
- $\text{Im}(X_t) = \{0, 1\}$
- This is an example of discrete time, discrete state stochastic process.

2. Let  $X_t$  be the number of customers in a store at time  $t$ .

at any time ( $t$ )  
 $X_t$  can take  
on values  
 $3, 0, 1, 2, 3, \dots$

- The time  $t \in \mathcal{T}$  where  $\mathcal{T} = (0, \infty)$
- $\text{Im}(X_t) = \{0, 1, 2, 3, \dots\}$
- This is an example of continuous time, discrete state stochastic process.

## Markov Chain

## Markov Chain (MC) and Markov Property

### Markov Property

A stochastic process  $X_t$  satisfies the **Markov property** if for any  $t_1 < t_2 < \dots < t_n < t$  and any sets  $A; A_1, \dots, A_n$ :

$$P\{X_t \in A | X_{t_1} \in A_1, \dots, X_{t_n} \in A_n\} = P\{X_t \in A | X_{t_n} \in A_n\}.$$

- The probability distribution of  $X_t$  at time  $t$  only depends on its previous state. (what happened right before it)
- If the above is satisfied, then  $X_t$  is called a **Markov Chain**.

5 / 16

### Markov Property Examples

1. A (fair) coin is flipped over and over: If coin lands on "heads", you win \$1. If coin lands on "tails", you lose \$1. Let  $X_t$  be your profit after  $t$  flips.

$$\begin{array}{rcl} H & \rightarrow & +\$1 \\ T & \rightarrow & -\$1 \end{array}$$

- $P(X_5 = 3 | X_4 = 2) = 0.5$
- $P(X_5 = 3 | X_4 = 2, X_3 = 1, X_2 = 2, X_1 = 1) = 0.5$

$X_t$  follows markov property  $\Rightarrow X_t$  is a markov chain

2. An urn contains 2 red balls, and 1 green ball. A ball is drawn (without replacement) from the urn yesterday and today. Another ball will be drawn tomorrow. Suppose you drew a red ball yesterday, and a red ball today.

- $P(\text{Red tomorrow} | \text{Red today}) = 0.5$
- $P(\text{Red tomorrow} | \text{Red today}, \text{Red yesterday}) = 0$

$X_t$  is not markov chain

b/c markov property not satisfied.

6 / 16

# Discrete-Time Discrete-State MC

## Discrete-Time Discrete-State Markov Chain (MC)

Suppose we have a Markov chain with time set  $\mathcal{T} = \{0, 1, 2, \dots\}$  and state space  $\{0, 1, 2, \dots\}$ . Two things we need to know about  $X_t$ :

1. **Initial distribution ( $P_0$ )**:  $P_0(x) = P(X_0 = x)$  usually given as a vector of probabilities for the initial states of  $X_t$ .  
Ex: State space =  $\{0, 1, 2\}$ ;  $P_0 = \{0.3, 0.4, 0.3\}$

"starting  
probabilities"

2. **Transition probabilities**:

→ **1-step** transition probability: probability of moving from state  $i$  to state  $j$  in 1 step.

$$p_{ij} = P(X_{t+1} = j | X_t = i)$$

**$h$ -step** transition probability: probability of moving from state  $i$  to state  $j$  in  $h$  steps.

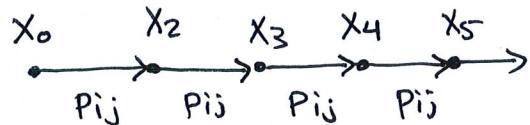

$$p_{ij}^{(h)} = P(X_{t+h} = j | X_t = i)$$

Ex  $p_{ij}^{(2)}$  = probability of moving from state  $i$  to  $j$  in 2 steps

## Discrete-Time Discrete-State Markov Chain (MC)

- We assume that the Markov Chain (MC) is *homogeneous*.  
(ie) transition probabilities  $p_{ij}$  are independent of  $t$ .  
→ For all times  $t_1, t_2 \in \mathcal{T}$ ,  $p_{ij}(t_1) = p_{ij}(t_2)$ .
- Then, the distribution of a homogeneous MC is completely determined by the initial distribution ( $P_0$ ) and one-step transition probability ( $p_{ij}$ ).

**Main Idea:** Start with an initial distribution  $P_0$ . Then use the one-step transition probability  $p_{ij}$  to “jump” forward to the next step. Then, we can keep going forward one step at a time.

8 / 16

## Examples

---

## Example

Example 1: In the summer, each day in Ames is either sunny or rainy. A sunny day is followed by another sunny day with probability 0.7, whereas a rainy day is followed by a sunny day with probability 0.4. It rains on Monday. Make weather forecasts for Tuesday and Wednesday.

Let 1 = "Sunny" and 2 = "Rainy".

To simplify and solve these types of problems, use transition matrices and matrix multiplication.

First we will solve w/o matrices. Then show that it's much easier w/ matrices.

RV:  $X_t$  = Weather on day t

State space =  $\begin{matrix} 1 \\ \uparrow \\ \text{sunny} \end{matrix}, \begin{matrix} 2 \\ \uparrow \\ \text{rainy} \end{matrix}$

9 / 16

Start on Monday: We know it rains on Monday

(Mon)	(sunny)	(rainy)
$x_0$	1	2
$P(x_0)$	0	1

Initial Distribution  $P_0$  of  $x_0$  (Monday)

$$P_0 = [0 \ 1]$$

Transition Probabilities ( $P_{ij}$  where  $i = \text{current}, j = \text{future}$ )

- $P_{11} = P(X_{t+1} = 1 | X_t = 1) = 0.7 \quad P(\text{Sunny} | \text{Sunny})$
- $P_{12} = P(X_{t+1} = 2 | X_t = 1) = 1 - P_{11} = 0.3 \quad P(\text{Rainy} | \text{Sunny})$
- $P_{21} = P(X_{t+1} = 1 | X_t = 2) = 0.4 \quad P(\text{Sunny} | \text{Rainy})$
- $P_{22} = P(X_{t+1} = 2 | X_t = 2) = 1 - P_{21} = 0.6 \quad P(\text{Rainy} | \text{Rainy})$

Forecast for Tuesday (1-step ahead)

$$P(\text{Tues Sunny} | \text{Mon Rainy}) = 0.4 = P_{21}$$

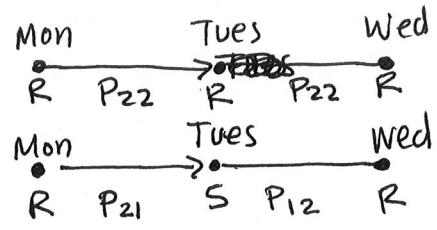

$$P(\text{Tues Rainy} | \text{Mon Rainy}) = 0.6 = P_{22}$$

(Tues)	(sunny)	(rainy)
$x_1$	1	2
$P(x_1)$	0.4	0.6

~~Prediction~~ Prediction: 60% chance of rain on Tues  
40% chance of sun on Tues.

10 / 16

## • Forecast for Wednesday

(Wed) (sun) (rain)

$x_2$	1	2
$P(x_2)$	0.52	0.48

$$\begin{aligned} & \text{P(Wed Rainy} \mid \text{Mon Rainy}) \\ &= P_{22}P_{22} + P_{21}P_{12} \end{aligned}$$

$$\begin{aligned} &= (0.6)^2 + (0.4)(0.3) \\ &= 0.48 \end{aligned}$$

$$\text{P(Wed Sunny} \mid \text{Mon Rainy})$$

$$\begin{aligned} &= 1 - 0.48 \\ &= 0.52 \end{aligned}$$

48% chance of rain on wednesday

52% chance of sun on wednesday

We can continue like this (moving forward one step at a time) to make predictions<sup>11/16</sup> for all future days  
But it will get increasingly complicated.

Simplify & avoid mistakes by using transition matrices.

## 1-Step Transition Probability Matrix

For a homogeneous MC with state space  $\{1, 2, \dots, n\}$ , the **1-step transition probability matrix** is:

$$P = \begin{pmatrix} 1 & 2 & \dots & n \\ p_{11} & p_{12} & \dots & p_{1n} \\ p_{21} & p_{22} & \dots & p_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ p_{n1} & p_{n2} & \dots & p_{nn} \end{pmatrix}.$$

Inside is  
 $p_{ij}$  where  
 $i =$  current  
 $j =$  future states

The element from the  $i$ -th row and  $j$ -th column is  $p_{ij}$ , which is the transition probability from state  $i$  to state  $j$ .

13 / 16

## $h$ -Step Transition Probability Matrix

Similarly, one can define a  $h$ -step transition probability matrix

$X_t = RV$

state space = {1, 2, 3}

$$P_0 = [0.3 \ 0.3 \ 0.4] \leftarrow \begin{array}{l} \text{Initial} \\ \text{Distribution} \end{array}$$

$$P^{(h)} = \begin{pmatrix} p_{11}^{(h)} & p_{12}^{(h)} & \dots & p_{1n}^{(h)} \\ p_{21}^{(h)} & p_{22}^{(h)} & \dots & p_{2n}^{(h)} \\ \vdots & \vdots & \ddots & \vdots \\ p_{n1}^{(h)} & p_{n2}^{(h)} & \dots & p_{nn}^{(h)} \end{pmatrix}.$$

1-step transition

$$P = \begin{bmatrix} 0.1 & 0.3 & 0.6 \\ 0.2 & 0.2 & 0.6 \\ 0.4 & 0.6 & 0 \end{bmatrix}_{3 \times 3}$$

Using the matrix notation the following results follow:

Predict 1-step ahead

- 2-step transition matrix  $P^{(2)} = P \cdot P = P^2$
- $h$ -step transition matrix  $P^{(h)} = P^h = \underbrace{P \cdot P \cdots P}_n$

$= P_0 P$

Predict 2 step ahead

$$= P_0 P^{(2)} = P_0 \cdot P \cdot P$$

The distribution of  $X_h$  ( $h$ -steps in the future) is  $P_h = \underbrace{P_0 P^h}_{\text{Ending Distribution}}$

14 / 16

## Example

Back to Example 1: We can solve the problem much more easily by using transition matrices ....

$$P = \begin{pmatrix} 0.7 & 0.3 \\ 0.4 & 0.6 \end{pmatrix} = \begin{pmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{pmatrix}$$

$$P^{(2)} = P \cdot P = \begin{pmatrix} 0.7 & 0.3 \\ 0.4 & 0.6 \end{pmatrix} \cdot \begin{pmatrix} 0.7 & 0.3 \\ 0.4 & 0.6 \end{pmatrix} = \begin{pmatrix} 0.61 & 0.39 \\ 0.52 & 0.48 \end{pmatrix}$$

$$P^{(3)} = P \cdot P \cdot P = \begin{pmatrix} 0.61 & 0.39 \\ 0.52 & 0.48 \end{pmatrix} \cdot \begin{pmatrix} 0.7 & 0.3 \\ 0.4 & 0.6 \end{pmatrix} = \begin{pmatrix} 0.583 & 0.417 \\ 0.556 & 0.444 \end{pmatrix}$$

Recall : state space =  $\begin{matrix} 1 \\ 2 \end{matrix}$   
 ↗ sun      ↙ rain

Mon : Initial Distribution  $P_0$  (We know 100% rain on Monday)

$$P_0 = [0 \ 1]$$

$$\begin{array}{c|cc} x_0 & 1 & 2 \\ \hline P(x_0) & 0 & 1 \end{array}$$

15 / 16

Tues 1-step ahead Prediction

$$P_0 \cdot P = [0 \ 1] \begin{matrix} 1 \times 2 \\ \begin{bmatrix} 0.7 & 0.3 \\ 0.4 & 0.6 \end{bmatrix} \\ 2 \times 2 \end{matrix} = \begin{matrix} (\text{sun}) & (\text{rain}) \\ [0.4 \ 0.6] \end{matrix}_{1 \times 2}$$

$$\begin{array}{c|cc} x_1 & 1 & 2 \\ \hline P(x_1) & 0.4 & 0.6 \end{array}$$

Wed 2-step ahead Prediction

$$\begin{aligned} P_0 P^{(2)} &= P_0 \cdot P \cdot P \\ &= [0 \ 1] \begin{bmatrix} 0.61 & 0.39 \\ 0.52 & 0.48 \end{bmatrix} = \begin{bmatrix} 0.52 & 0.48 \end{bmatrix} \end{aligned}$$

$$\begin{array}{c|cc} x_2 & 1 & 2 \\ \hline P(x_2) & 0.52 & 0.48 \end{array}$$

$$P(\text{Wed Rain} \mid \text{Mon Rain}) = 0.48$$

$$P(\text{Wed Sun} \mid \text{Mon Rain}) = 0.52$$

Thurs 3-steps ahead Prediction

$$P_0 P^{(3)} = P_0 \cdot P \cdot P \cdot P = [0.556, 0.444]$$

16 / 16
